

Incident report analysis

Summary	On (Date), (company), noted that regular network services were not responding. It appears a large quantity of ICMP packet requests were being received from a number of IPs, known as a DDOS attack. To stop the attack, the team shut down traffic to non-critical services and adjusted network security configurations.
Identify	A thorough investigation of the company's systems and processes was conducted to determine any security gaps. It appears the firewall was not provided with a packet limit to slow incoming network traffic or to check incoming packets for spoofed IP addresses.
Protect	The team has updated the firewall's configuration set a rule that would limit the rate of incoming ICMP packets.
Detect	To detect DDOS attacks in the future, the team set network monitoring software to proactively scan for abnormal traffic patterns, set the firewall to check for IP spoofing on incoming ICMP packets, and implemented an IDS/IPS system to filter out suspicious ICMP packets. The team will use a SIEM program to aggregate and monitor alerts received by these tools.
Respond	The team will monitor SIEM logs to check for suspicious and abnormal activity. The team will also report all incidents to upper management and appropriate legal authorities, if applicable. Regular security audits will be conducted to update and maintain configurations.
Recover	The incident management team responded by blocking incoming ICMP packets, stopping all non-critical network services offline, and restoring critical network services. Regular network operations have been restored.
